LME49724
High Performance, High Fidelity, Fully-Differential Audio Operational Amplifier

General Description
The LME49724 is an ultra-low distortion, low noise, high slew rate fully-differential operational amplifier optimized and fully specified for high performance, high fidelity applications. Combining advanced leading-edge process technology with state of the art circuit design, the LME49724 fully-differential audio operational amplifier delivers superior audio signal amplification for outstanding audio performance. The LME49724 combines extremely low voltage noise density (2.1nV/√Hz) with vanishingly low THD+N (0.00003%) to easily satisfy the most demanding audio applications. To ensure that the most challenging loads are driven without compromise, the LME49724 has a high slew rate of ±18V/µs and an output current capability of ±80mA. Further, dynamic range is maximized by an output stage that drives 600Ω loads to 52V P-P while operating on a ±15V supply voltage. The LME49724’s outstanding CMRR (102dB), PSRR (125dB), and VOS (0.2mV) results in excellent operational amplifier DC performance.

The LME49724 has a wide supply range of ±2.5V to ±18V. Over this supply range the LME49724’s input circuitry maintains excellent common-mode and power supply rejection, as well as maintaining its low input bias current. The LME49724 is unity gain stable. This Fully-Differential Audio Operational Amplifier achieves outstanding AC performance while driving complex loads with capacitive values as high as 100pF.

Key Specifications
- Power Supply Voltage Range: ±2.5V to ±18V
- THD+N
  \( A_v = 1, \ V_{\text{OUT}} = 3V_{\text{RMS}}, f_{\text{IN}} = 1\text{kHz} \)
  \[ R_L = 2k\Omega \]
  \[ 0.00003\% \text{ (typ)} \]

Features
- Drives 600Ω loads with full output signal swing
- Optimized for superior audio signal fidelity
- Output short circuit protection
- PSRR and CMRR exceed 100dB (typ)
- Available in PSOP package

Applications
- Ultra high quality audio amplification
- High fidelity preamplifiers and active filters
- Simple single-ended to differential conversion
- State of the art D-to-A converters
- State of the art A-to-D input amplifiers
- Professional Audio
- High fidelity equalization and crossover networks
- High performance line drivers and receivers

| C_LOAD  | Capacitive Load Drive Overshoot | C_L = 100pF | 5 | | % |

**Note 1:** Absolute Maximum Ratings indicate limits beyond which damage to the device may occur, including inoperability and degradation of device reliability and/or performance. Functional operation of the device and/or non-degradation at the Absolute Maximum Ratings or other conditions beyond those indicated in the Recommended Operating Conditions is not implied. The Recommended Operating Conditions indicate conditions at which the device is functional and the device should not be operated beyond such conditions. All voltages are measured with respect to the ground pin, unless otherwise specified.

**Note 2:** The Electrical Characteristics tables list guaranteed specifications under the listed Recommended Operating Conditions except as otherwise modified or specified by the Electrical Characteristics Conditions and/or Notes. Typical specifications are estimations only and are not guaranteed.

**Note 3:** The maximum power dissipation must be derated at elevated temperatures and is dictated by $\frac{P_{DMAX}}{T_{JMAX}} = \frac{T_{JMAX} - T_A}{T_{JMAX}}$. The maximum allowable power dissipation is $P_{DMAX} = \frac{T_{JMAX}}{T_A}$. The maximum allowable power dissipation is $P_{DMAX} = \frac{T_{JMAX}}{T_A}$ or the number given in Absolute Maximum Ratings, whichever is lower.

**Note 4:** Human body model, applicable std. JESD22-A114C.

**Note 5:** Machine model, applicable std. JESD22-A115-A.

**Note 6:** Typical values represent most likely parametric norms at $T_A = +25^\circ$C, and at the Recommended Operation Conditions at the time of product characterization and are not guaranteed.

**Note 7:** Datasheet min/max specification limits are guaranteed by test or statistical analysis.

**Note 8:** PSRR is measured as follows: $V_{OS}$ is measured at two supply voltages, ±5V and ±15V. PSRR = $|20\log_{10}(\Delta V_{OS}/\Delta V_s)|$.

**Note 9:** The ENABLE threshold voltage is determined by $V_{BE}$ voltages and will therefore vary with temperature. The typical values represent the most likely parametric norms at $T_A = +25^\circ$C.

80kHz BW

Supply Current vs Supply Voltage

\[ V_{IN} = 0V, \; R_L = \text{No Load} \]
**Application Information**

**GENERAL OPERATION**

The LME49724 is a fully differential amplifier with an integrated common-mode reference input (V\textsubscript{OCM}). Fully differential amplification provides increased noise immunity, high dynamic range, and reduced harmonic distortion products. Differential amplifiers typically have high CMRR providing improved immunity from noise. When input, output, and supply line trace pairs are routed together, noise pickup is common and easily rejected by the LME49724. CMRR performance is directly proportional to the tolerance and matching of the gain configuring resistors. With 0.1% tolerance resistors the worst case CMRR performance will be about 60dB (20\text{LOG}(0.001)).

A differential output has a higher dynamic range than a single-ended output because of the doubling of output voltage. The dynamic range is increased by 6dB as a result of the outputs being equal in magnitude but opposite in phase. As an example, a single-ended output with a 1V\text{PP} signal will be two 1V\text{PP} signals with a differential output. The increase is 20\text{LOG}(2) = 6dB. Differential amplifiers are ideal for low voltage applications because of the increase in signal amplitude relative to a single-ended amplifier and the resulting improvement in SNR.

Differential amplifiers can also have reduced even order harmonics, all conditions equal, when compared to a single-ended amplifier. The differential output causes even harmonics to cancel between the two inverted outputs leaving only the odd harmonics. In practice even harmonics do not cancel completely, however there still is a reduction in total harmonic distortion.

**OUTPUT COMMON-MODE VOLTAGE (V\textsubscript{OCM} pin)**

The output common-mode voltage is the DC voltage on each output. The output common-mode voltage is set by the V\textsubscript{OCM} pin. The V\textsubscript{OCM} pin can be driven by a low impedance source. If no voltage is applied to the V\textsubscript{OCM} pin, the DC common-mode output voltage will be set by the internal resistor divider to the midpoint of the voltages on the V\textsubscript{CC} and V\textsubscript{EE} pins. The input impedance of the V\textsubscript{OCM} pin is 50k\textOmega. The V\textsubscript{OCM} pin can be driven up to V\textsubscript{CC} - 1.5V and V\textsubscript{EE} + 1.5V. The V\textsubscript{OCM} pin should be bypassed to ground with a 0.1\textmu F to 1\textmu F capacitor. The V\textsubscript{OCM} pin should be connected to ground when the desired output common-mode voltage is ground reference. The value of the external capacitor has an effect on the PSRR performance of the LME49724. With the V\textsubscript{OCM} pin only bypassed with a low value capacitor, the PSRR performance of the LME49724 will be reduced, especially at low audio frequencies. For best PSRR performance, the V\textsubscript{OCM} pin should be connected to stable, clean reference. Increasing the value of the bypass capacitor on the V\textsubscript{OCM} pin will also improve PSRR performance.

**ENABLE FUNCTION**

The LME49724 can be placed into standby mode to reduce system current consumption by driving the ENABLE pin below V\textsubscript{EE} + 1.75V. The LME49724 is active when the voltage on the ENABLE pin is above V\textsubscript{EE} + 2.35V. The ENABLE pin should not be left floating. For best performance under all conditions, drive the ENABLE pin to the V\textsubscript{EE} pin voltage to enter standby mode and to ground for active operation when operating from split supplies. When operating from a single supply, drive the ENABLE pin to ground for standby mode and to V\textsubscript{CC} for active mode.

**FULLY DIFFERENTIAL OPERATION**

The LME49724 performs best in a fully differential configuration. The circuit shown in Figure 2 is the typical fully differential configuration.

**FIGURE 2. Fully Differential Configuration**

The closed-loop gain is shown in Equation 1 below.

\[ A_V = \frac{R_F}{R_i} \quad \text{(V/V)} \]  

Where \( R_{f1} = R_{f2}, R_{i1} = R_{i2} \). Using low value resistors will give the lowest noise performance.

**SINGLE-ENDED TO DIFFERENTIAL CONVERSION**

For many applications, it is required to convert a single-ended signal to a differential signal. The LME49724 can be used for a high performance, simple single-to-differential converter. Figure 3 shows the typical single-to-differential converter circuit configuration.

**FIGURE 3. Single-Ended Input to Differential Output**
SINGLE SUPPLY OPERATION
The LME49724 can be operated from a single power supply, as shown in Figure 4. The supply voltage range is limited to a minimum of 5V and a maximum of 36V. The common-mode output DC voltage will be set to the midpoint of the supply voltage. The \( V_{OCM} \) pin can be used to adjust the common-mode output DC voltage on the outputs, as described previously, if the supply voltage midpoint is not the desired DC voltage.

![Figure 4. Single Supply Configuration](image)

DRIVING A CAPACITIVE LOAD
The LME49724 is a high speed op amp with excellent phase margin and stability. Capacitive loads up to 100pF will cause little change in the phase characteristics of the amplifiers and are therefore allowable. Capacitive loads greater than 100pF must be isolated from the output. The most straightforward way to do this is to put a resistor in series with the output. This resistor will also prevent excess power dissipation if the output is accidentally shorted.

THERMAL PCB DESIGN
The LME49724's high operating supply voltage along with its high output current capability can result in significant power dissipation. For this reason the LME49724 is provided in the exposed DAP MSOP (PSOP) package for improved thermal dissipation performance compared to other surface mount packages. The exposed pad is designed to be soldered to a copper plane on the PCB which then acts as a heat sink. The thermal plane can be on any layer by using multiple thermal vias under and outside the IC package. The vias under the IC should have solder mask openings for the entire pad under the IC on the top layer but cover the vias on the bottom layer. This method prevents solder from being pulled away from the thermal vias during the reflow process resulting in optimum thermal conductivity. Heat radiation from the PCB plane area is best accomplished when the thermal plane is on the top or bottom copper layers. The LME49724 should always be soldered down to a copper pad on the PCB for both optimum thermal performance as well as mechanical stability.

The exposed pad is for heat transfer and the thermal plane should either be electrically isolated or connected to the same potential as the \( V_{EE} \) pin. For high frequency applications (\( f > 1\)MHz) or lower impedance loads, the pad should be connected to a plane that is connected to the \( V_{EE} \) potential.

SUPPLY BYPASSING
The LME49724 should have its supply leads bypassed with low-inductance capacitors such as leadless surface mount (SMT) capacitors located as close as possible to the supply pins. It is recommended that a 10\( \mu \)F tantalum or electrolytic capacitor be placed in parallel with a 0.1\( \mu \)F ceramic or film type capacitor on each supply pin. These capacitors should be star routed with a dedicated ground return plane or large trace for best THD performance. Placing capacitors too far from the power supply pins, especially with thin connecting traces, can lead to excessive inductance, resulting in degraded high-frequency bypassing. Poor high-frequency bypassing can result in circuit instabilities. When using high bandwidth power supplies, the value and number of supply bypass capacitors should be reduced for optimal power supply performance.

BALANCE CABLE DRIVER
With high peak-to-peak differential output voltage and plenty of low distortion drive current, the LME49724 makes an excellent balanced cable driver. Combining the single-to-differential configuration with a balanced cable driver results in a high performance single-ended input to balanced line driver solution. Although the LME49724 can drive capacitive loads up to 100pF, cable loads exceeding 100pF can cause instability. For such applications, series resistors are needed on the outputs before the capacitive load.

ANALOG-TO-DIGITAL CONVERTER (ADC) APPLICATION
Figure 5 is a typical fully differential application circuit for driving an analog-to-digital converter (ADC). The additional components of \( R_5 \), \( R_6 \), and \( C_7 \) are optional components and are for stability and proper ADC sampling. ADC's commonly use switched capacitor circuitry at the input. When the ADC samples the signal the current momentarily increases and may disturb the signal integrity at the sample point causing a signal glitch. Component \( C_7 \) is significantly larger than the input capacitance of a typical ADC and acts as a charge reservoir greatly reducing the effect of the signal sample by the ADC. Resistors \( R_5 \) and \( R_6 \) decouple the capacitive load, \( C_7 \), for stability. The values shown are general values. Specific values should be optimized for the particular ADC loading requirements.

The output reference voltage from the ADC can be used to drive the \( V_{OCM} \) pin to set the common-mode DC voltage on the outputs of the LME49724. A buffer may be needed to drive the LME49724's \( V_{OCM} \) pin if the ADC cannot drive the 50k\( \Omega \) input impedance of the \( V_{OCM} \) pin.

In order to minimize circuit distortion when using capacitors in the signal path, the capacitors should be comprised of either NPO ceramic, polystyrene, polypropylene or mica composition. Other types of capacitors may provide a reduced distortion performance but for a cost improvement, so capacitor selection is dependent upon design requirements. The performance/cost tradeoff for a specific application is left up to the user.
DISTORTION MEASUREMENTS

The vanishing low residual distortion produced by the LME49724 is below the capabilities of commercially available equipment. This makes distortion measurements more difficult than simply connecting a distortion meter to the amplifier’s inputs and outputs. The solution, however, is quite simple: an additional resistor. Adding this resistor extends the resolution of the distortion measurement equipment.

The LME49724’s low residual distortion is an input referred internal error. As shown in Figure 6, adding a resistor connected between the amplifier’s inputs changes the amplifier’s noise gain. The result is that the error signal (distortion) is increased. Although the amplifier’s closed-loop gain is unaltered, the feedback available to correct distortion errors is reduced, which means that measurement resolution increases. To ensure minimum effects on distortion measurements, keep the value of $R_5$ low. The distortion reading on the audio analyzer must be divided by a factor of $(R_3 + R_4)/R_5$, where $R_1 = R_2$ and $R_3 = R_4$, to get the actual measured distortion of the device under test. The values used for the LME49724 measurements were $R_1, R_2, R_3, R_4 = 1k\Omega$ and $R_5 = 20\Omega$.

This technique is verified by duplicating the measurements with high closed-loop gain and/or making the measurements at high frequencies. Doing so produces distortion components that are within the measurement equipment’s capabilities.

* Value is application and converted dependent.

FIGURE 5. Typical Analog-to-Digital Converter Circuit
PERFORMANCE VARIATIONS
The LME49724 has excellent performance with little variation across different supply voltages, load impedances, and input configuration (single-ended or differential). Inspection of the THD+N vs Frequency and THD+N vs Output Voltage performance graphs reveals only minimal differences with different load values. Figures 7 and 8 below show the performance across different supply voltages with the same output signal level and load. Figure 7 has plots at ±5V, ±12V, ±15V, and ±18V with a 3V\(_{\text{RMS}}\) output while Figure 8 has plots at ±12V, ±15V, and ±18V with a 10V\(_{\text{RMS}}\) output. Both figures use a 600Ω load. The performance for each different supply voltage under the same conditions is so similar it is nearly impossible to discern the different plots lines.

Whether the input configuration is single-ended or differential has only a minimal affect on THD+N performance at higher audio frequencies or higher signal levels. For easy comparison, Figures 9 and 10 are a combination of the performance graphs found in the Typical Performance Characteristics section above.
FIGURE 9. THD+N vs FREQUENCY with $R_L = 10k\Omega$
$V_{OUT} = 3V_{RMS}$, $V_S = \pm15V$, 80kHz BW
Single-ended and Differential Input

$V_S = \pm2.5V$, $\pm15V$, and $\pm18V$, 80kHz BW

FIGURE 10. THD+N vs OUTPUT VOLTAGE with $R_L = 10k\Omega$
$f = 20Hz$, $1kHz$, $20kHz$, $V_S = \pm15V$, 80kHz BW
Single-ended and Differential Input

Power Supply Rejection Ratio does not vary with load value nor supply voltage. For easy comparison, Figures 11 and 12 below are created by combining performance graphs found in the Typical Performance Characteristics section above.

FIGURE 11. PSRR vs FREQUENCY with $R_L = 600\Omega$

$V_S = \pm2.5V$, $\pm15V$, and $\pm18V$, 80kHz BW

FIGURE 12. PSRR vs FREQUENCY with $V_S = \pm15V$
$R_L = 600\Omega$, $2k\Omega$, and $10k\Omega$, 80kHz BW

Although supply current may not be a critical specification for many applications, there is also no real variation in supply current with no load or with a 600$\Omega$ load. This is a result of the extremely low offset voltage, typically less than 1mV. Figure 13 shows the supply current under the two conditions with no real difference discernable.
